

## VERMI-WASH

Earthworm secretions and castings contain a liquid called drilospheres which enables them to move through the soil and digests their food. This liquid is nutrient and bacteria rich and promotes plant growth. In order to collect this liquid we use a vermi-bin.

**The entire set up may be reset after 10-12 months.**

The excess water that comes out of vermi-bin is liquid manure called **Vermi-wash**. Vermi-wash is a plant growth regulator which contains high amounts of enzymes, vitamins and hormones like auxins, gibberellins and others along with macro and micro-nutrients.

For making 1 litre of Vermi wash - 1 litre of cow's urine and 8 litres of water are added.
